

# Erosion and Dilation

November 28, 2020

## Introduction

The task consists to implement a couple of basic image processing operations. The erosion and dilation algorithm are a well-known basic morphologic operation, which can be combined for edge detection. For this case, the mask is defined as a squared 5x5 kernel for erosion (table 1) and dilation (table 2). An input signal will be used as switch to select between both filters or the edge detector.

## Description

The final code must be able to receive a stream of pixels from an image and to generate an output image with its edge. The data to be processed would be pixels from a BMP file (RGB = 3 bytes/pixel). The image must firstly be converted to grayscale before generating the final output image. The user must select what output to deliver: erosion, dilation or the edge of the input image. The edge is obtained by subtracting the erode and the dilate image. As a result, two designs with optimizations targeting performance or area must be created. Furthermore, at least one optimization at function, loop and I/O level must be applied to each design.

The student will be provided with a reference C/C++ code to manipulate BMP images and to test her/his Vivado HLS code (High-Level test bench).

A final report (up to 10 pages) must be delivered together with all the Vivado HLS code. In the report, you must detail and justify the used optimizations and to provide a complete table comparing the results obtained for each optimization. This table must report the latency, the execution time, the maximum

|   |   |   |   |   |
|---|---|---|---|---|
| 1 | 0 | 1 | 0 | 1 |
| 0 | 1 | 1 | 1 | 0 |
| 1 | 1 | 1 | 1 | 1 |
| 0 | 1 | 1 | 1 | 0 |
| 1 | 0 | 1 | 0 | 1 |

Table 1: Convolutional kernel for Erosion 5x5.

|   |   |   |   |   |
|---|---|---|---|---|
| 0 | 1 | 0 | 1 | 0 |
| 1 | 1 | 1 | 1 | 1 |
| 0 | 1 | 1 | 1 | 0 |
| 1 | 1 | 1 | 1 | 1 |
| 0 | 1 | 0 | 1 | 0 |
